Analysis, Review, and Documentation
of the Activation Data from LDEF Material

NASA Contract # H-08071D

by

Dr. C. E. Laird
Professor of Physics
Eastern Kentucky University

Samples removed from LDEF-1 are being studied at various laboratories to determine the specific activity(pCi/kg) produced in orbit by exposure to protons and neutrons in near-Earth orbit. These activities are being corrected for efficiency, self-attenuation, and background. The activities and associated gamma-ray spectra are being collected, analyzed, documented and reviewed by faculty and graduate students at Eastern Kentucky University. The currently available activation results have been tabulated and reviewed in this report. Approximately 500 spectra have been accumulated for future archival and analysis. The effect of the changing satellite orbit on the activation is reported herein and was calculated using more recent estimates of the flux of Van Allen belt protons.

Final Technical Report

NASA Contract H-08071D

INTRODUCTION

Since retrieval in January, 1990, almost 400 samples from the LDEF-1 spacecraft have been studied to ascertain the activation induced by exposure to the radiation environment of space. These samples have been studied with low-background gamma-ray spectrometers at Marshall Space Flight Center (MSFC) and at seven other counting laboratories to carefully measure specific activities(activity per unit mass). Eastern Kentucky University (EKU) has been active in providing analytical support to these laboratories and in the interpretation of the resulting activities. National Aeronautics and Space Administration(NASA) Contract #H-08071D provided funding for the EKU participation as a continuation and expansion of the studies previously supported by contracts NAS8-35180 and NAS8-36642. Specifically, NASA contract #H-08071D required the following statement of work:

The contractor shall perform the following studies and provide calculations related to the induced radioactivity of metal samples returned from the LDEF-1 mission.

1. Using gamma-ray spectra obtained post-flight from LDEF samples at the counting laboratories, derive net activities due to radioisotopes detected in the samples. Corrections for geometry, self-absorption, detector efficiency and background shall be made. Uncertainties of the net rate due to counting statistics and experimental errors shall be estimated. Quarterly progress reports and a copy of the final report will be required to be delivered to the addresses indicated in Attachment J-2 of the Purchase Order.

2. The saturation activity, averaged over the mission, shall be determined for each radioisotope, measured in disintegrations per second per kilogram of material for selected samples.

3. Using experimentally-determined activation cross sections estimates shall be made of the fluxes of activating protons and neutrons, averaged over the mission lifetime at various locations within the LDEF spacecraft.

In fulfillment of this statement of work, this report includes:

1. a tabulation of the specific activities measured from samples sent to Lawrence Berkeley Laboratory(LBL), Los Alamos National Laboratory(LANL), Lawrence Livermore Laboratory(LLL), Savannah River Laboratory(SRL), the Tennessee Valley Authority Western Area Radiological Laboratory(TVA), and Battelle Memorial Institute Pacific Northwest Laboratory(PNWL). These activities have been corrected for geometry, efficiency, self absorption and background. They are decay corrected to the designated retrieval date of January 20, 1990. The associated errors are given. The principal investigator is uncertain as to whether or not the specific activities from TVA include the attenuation corrections. Specific activities and spectra have not been received for samples studied at Johnson Space Center(JSC). Spectra have not been received from TVA, LBL, PNWL, and LANL. Also, the results from PNWL are not complete.

2. an initial tabulation of the specific activities resulting from the analysis of gamma-ray spectra taken at MSFC. These results are corrected for geometry, efficiency, self absorption and background and are decay corrected to 1/20/90. This tabulation has been sent to Alan Harmon at MSFC for his evaluation and response.

3. the expected activation for the LDEF samples calculated using the proton fluxes supplied by John Watt of MSFC for an orbit with a 28.5° inclination at an altitude of 172 nautical miles during a period of maximum solar activity. This, coupled with previous calculation^{1,2}, gives an estimated range of saturation activities for the LDEF samples. However, a better estimation of the activation requires a more careful calculation using proton fluxes appropriate to the rapidly decaying orbit of LDEF and the change over the mission from a period of minimum to one of maximum solar activity.

4. the expected activation at 172 nautical miles (nmi) calculated using new estimates of the proton and neutron fluxes

encountered by LDEF. However, more accurate flux estimates require activation calculations taking into account the changing orbital altitude and the changing solar activity as mentioned in (3) above.

The results presented in this report are limited by the incomplete nature of the reports of sample activities measured at the counting laboratories. As of June 21, 1992, extensive reports of specific activities have been received only from LLNL, SRL, LANL, and LBL. Analysis of the MSFC data is nearing completion, but we(EKU) have received neither specific activities nor gamma-ray spectra from PNWL, JSC, or TVA. Except for the MSFC specific activities, the compiled results will be discussed in the following sections.

As was the case with the report on NASA Contract # NAS8-36649, a peripheral result of this study has been the interaction with university students and with a neighboring institution. Over the past year four graduate students and two undergraduates have participated in this project. Also, the principal investigator gave a presentation at Western Kentucky University describing the LDEF-1 induced-activation study.

I. TABULATED SPECIFIC ACTIVITIES

The scientific investigator and the associated laboratory participating in the sample counting are listed in Table 1. The tabulated specific activities with associated error from those laboratories that have submitted them to EKU are listed in Table 2. Results from MSFC are not included because the final results from the EKU analysis of the spectra have to be reviewed by Dr. Alan Harmon. Some of these analytical results have been reported elsewhere(ref. 3-5).

Figures 1-10 gives graphical representations of this data for comparison. Figure 1 shows a composite of the specific activations with associated errors for the LH trunnion as a function of depth along the axis of the trunnion. The legend identifies the scientific investigator for the data points. Because the data is not currently available, direct comparisons for a specific section are not given. However, indications of the expected trend of decreasing activation down the length of the trunnion are evident. Considerable

nonstatistical fluctuations from this trend are seen not only among the data from different laboratories but also from within one data set(Camp/McLean). These variations should be given further study in consultation with the scientific investigators.

Figure 2 shows the consistency of the activation for several layers of the LHD trunnion section(earth end) independently measured by Moss and Reedy at LANL. Figure 3 shows that the activation on the two sides of a trunnion section are different as would be expected if there was a larger flux of incident particles on one side than on the other, or a diminution of the flux by passage through the section. Figure 4 shows the decreasing activation of a trunnion layer as a function of the radial distance into the RHG section, and also indicates that there is a greater incident flux on the earth(ER) side than on the space(SP). Figure 5 gives the same activation as a function of depth as in figure 4 for the south(S) and earth(E) except for the RHD section. Figure 6 is similar to fig. 3 except for the space end(SP) of RHG.

Figures 7-10 show the specific activities reported reported by Moss and Reedy at LANL. These two investigators performed essentially independent gamma-ray counting although there was some consultation concerning consistency of the results. Their final results are very consistent although the stated errors are quite large; especially for the first layer studied, layer 2. This data shows that the activation for the space end of both RHD and LHD is consistently smaller than for the earth end. Weighed averaging of these results would significantly reduce the associated error.

II. PROTON FLUX VARIATION AND PREDICTED ACTIVATION

During the sixty-eight months that LDEF-1 was in orbit, significant changes occurred in the flux of protons encountered in the region of the Van Allen Belt known as the South Atlantic Anomaly. These changes were caused by two factors. First, the original 258 nm orbit decreased at an accelerating rate reaching an altitude of 172 nm at retrieval. Second, around day 1400 in the mission a period of minimum solar activity ended and a period of maximum activity began. The subsequent swelling of the atmosphere of the earth caused a greater resistance to the motion of LDEF-1 and a greater

atmospheric interaction with Van Allen Belt protons. The net results of these processes was a decrease in proton flux encountered by the spacecraft. Figure 10 shows the flux of 50 MeV protons as a function of time in orbit taking into account the solar effects listed above⁶. Figure 11 shows the associated production of ⁵⁴Mn. Clearly evident in these plots are the significant changes in the production rate of spacecraft material.

The effect of this dropping production rate on the final specific activity of LDEF-1 materials is very profound. If the fluxes had been constant, then many isotopes with half-lives of less than about one or two years would have neared saturation by the time of retrieval. This saturated activity would have been closely associated with the flux (the number and energy) of activating particles. However, the final specific activities are strongly dependent on the rate of flux decrease with time at all energies. Predicting the expected activation, or determining the flux of activating particles, for LDEF-1 will require a detailed calculation which includes the accumulated daily activation and the decay of the calculated activity from each day until the day of retrieval.

Table 3 gives a summary of the expected activation on the day of retrieval. The fluxes are those supplied by Watts⁶ for the 172 nm orbit of LDEF-1 in January, 1990. The cross sections for nuclear reactions are the same as in refs. 1 and 2.
